

Logical ER Diagram — Unified Regulatory Reporting Platform

Business/conceptual data model. This view shows the *domain entities* the platform reasons about and how they relate — independent of how they are physically stored (CDC feeds, staging views, marts). One consistent model spans every domain and every jurisdiction; jurisdiction variance is carried as **data** (the `REGULATOR_CODE_MAP` and the `REG_ATTRIBUTE` extension carrier), never as per-market entities. See `ER-PHYSICAL.md` for the persisted tables and `DATA-FLOW.md` for how data moves between them.

Domains: **Accounts & Payments**, **Sports Betting, Gaming** (casino / poker / jackpots), **Operator Opt-in Jackpot**, **Player Protection**, and the **Regulatory / Nomenclature** reference spine.

Full logical model

How the model stays "write once, run every market"

Concern	Where variance lives	Why it is <i>not</i> a new entity
Different regulator codes for the same sport/game	<code>REGULATOR_CODE_MAP</code> rows, keyed by <code>jurisdiction</code> + <code>canonical</code>	A row, not a table — and effective-dated so history reproduces
A datum only one market needs (e.g. BG <code>nra_registration_id</code> , NL <code>cruks_check_ref</code>)	<code>REG_ATTRIBUTE</code> key-value rows + one extension-registry entry	The shared entities never widen; carrier absorbs the difference
Different tax rate, cadence, timezone, player-id treatment	<code>JURISDICTION</code> attributes (config)	Attributes on one entity, resolved at query time
Rate/code that changed on a date	<code>valid_from</code> / <code>valid_to</code> on the mapping + a rate schedule	Time is data; a resubmission of an old period is exact

The **breach entities** (deposit / loss / wallet-overspend / activity-while-excluded / unverified-withdrawal) are *derived* views over these entities that must always be empty — they are shown in `ER-PHYSICAL.md` and `DATA-FLOW.md` rather than here, because logically they are constraints, not stored business objects.
